| Mayo Clinic | Whether it's the serve, forehand, backhand or <br> volley, tennis puts a lot of stress on your wrist. |
|  | "There are about 18 million tennis players in the <br> United States. And when we talk about injuries in <br> the upper extremity, about 30\% in tennis players <br> are wrist injuries. That's a high number." |
|  | Many of those injuries are caused by chronic <br> overuse. |
|  | "The average tennis match, there's about over <br> 1,000 ground strokes. Now if you're practicing <br> three, four times a week, for two, three hours, <br> maybe not hit 1,000 shots. Maybe just practice on <br> volleying." |
|  | How you grip the racket and hit the ball plays a <br> major role, too, which is why Mayo researchers <br> recently studied tennis players' strokes in a motion <br> analysis lab. |
|  | "With our research, we've learned - just by looking <br> at the various muscles and motion capture <br> technology - we can really break it down to the <br> millisecond to see which muscles are firing <br> appropriately and which ones aren't." |
|  | "I've actually had patients who we've operated on, <br> they've gone through this program to see that <br> actually, when they're hitting a topspin, their wrist is <br> in the wrong position. That can't be picked up with <br> the naked eye. And now they can work with their <br> tennis professionals to improve their form to <br> hopefully prevent further injury." |
